# How to go from partial to full retroactivity in detail

Cristina G. Fernandes, Felipe C. de Noronha

IME-USP - Brazil

LAGOS 25 - November 10-14, 2025

- 1. Hello everyone. My name is Felipe Noronha, and today I'll be presenting the work done by Professor Cristina Fernandes and I at IME-USP.
- 2. Our paper details a method for transforming partially retroactive data structures into fully retroactive ones.
- 3. This work is motivated by a practical limitation in the well-known 2007 transformation by Demaine, Iacono, and Langerman and it also builds upon a 2022 solution by Junior and Seabra.
- Our key contribution is a method to achieve this transformation with the same time complexity, but \*without\* the need for complex persistent data structures.
- 5. To illustrate our approach, we'll use the minimum spanning forest problem as our main example. So, let's start by defining what that is.

#### What is a spanning tree?

- Let G = (V, E) be a connected graph
- **Spanning tree:** A tree with all vertices of *G*

Partial to full retroactivity

2025-10-30

─What is a spanning tree?

What is a spanning tree?

Let G = (V, E) be a connected graph

Spanning tree: A tree with all vertices of G

- 1. Lets start of by defining what is a spanning tree on a graph G with a set of vertices and edges
- 2. A spanning tree will be a tree will all the vertices of G
- 3. ——- SKIP SLIDE ——-
- 4. It will have 3 main properties: it is connected (path between any two vertices), acyclic (no cycles), contains exactly n-1 edges for n vertices
- 5. ——- SKIP SLIDE ——-
- Show visual example with graph G (blue edges) and spanning tree T (red wavy edges)
- 7. In the example: 8 vertices, so spanning tree has exactly 7 edges
- 8. Emphasize that spanning trees are not unique there can be many valid spanning trees

# What is a spanning tree?

- Let G = (V, E) be a connected graph
- **Spanning tree:** A tree with all vertices of *G*
- Properties:
  - Connected (path between any two vertices)
  - Acvclic (no cycles)
  - ightharpoonup Contains exactly n-1 edges for n vertices

# Minimum Spanning Tree and Forest

• Minimum Spanning Tree (MST): spanning tree in a weighted graph with minimum total cost

Partial to full retroactivity

2025-10-30

└─Minimum Spanning Tree and Forest

Minimum Spanning Tree and Forest

1. Now, let's add weights or costs to the edges. In a weighted graph, a Minimum Spanning Tree, or MST, is a spanning tree that has the minimum possible total cost. It's an optimization problem.

- 2. ——- SKIP SLIDE ——-
- 3. This concept generalizes to disconnected graphs as well. We call this a Minimum Spanning Forest, or MSF, which is simply the collection of MSTs for each connected component.
- 4. ——- SKIP SLIDE ——-
- 5. In the visual example, you can see the same graph as before, but now with costs on the edges. The red edges again show the tree, but this time, they've been chosen to be the MST.
- 6. If we sum the costs of the red edges, we get a total of 14. Any other spanning tree you could build for this graph would have a total cost greater than or equal to 14.
- 7. This idea of maintaining an optimal-cost forest is central to our problem. Specifically, how to maintain this optimality as the graph changes.

## Minimum Spanning Tree and Forest

- Minimum Spanning Tree (MST): spanning tree in a weighted graph with minimum total cost
- Minimum Spanning Forest (MSF): generalization for disconnected graphs

#### Incremental MSF problem

• Problem: Keep track of an MSF in a graph that grows over time

• Graph starts empty, edges are added one by one

Partial to full retroactivity

2025-1

☐Incremental MSF problem

Incremental MSF problem

Problem: Keep track of an MSF in a graph that gross over time

Graph starts empty, edges are added one by one

- 1. So, this brings us to the Incremental MSF problem. The goal is to maintain a Minimum Spanning Forest in a graph that grows over time.
- 2. Crucially, the graph starts empty, and edges are only added one by one.
- 3. ——- SKIP SLIDE ——-
- This problem is defined by two operations: add\_edge, which inserts a new weighted edge, and get\_msf, which returns the current minimum spanning forest.
- 5. ——- SKIP SLIDE ——-
- 6. The solution to this was given by Frederickson in 1983. He used a dynamic data structure called link-cut trees which achieves a  $O(\log n)$  amortized time per edge addition, where n is the number of vertices.

#### Incremental MSF problem

• Problem: Keep track of an MSF in a graph that grows over time

• Graph starts empty, edges are added one by one

#### Operations:

- ▶ add\_edge(u, v, w): add edge with cost w between vertices u and v
- get\_msf(): return a list with the edges of an MSF of G

Partial to full retroactivity

2025-10-30

Incremental MSF problem

Problem: Keep track of an MSF in a graph that grows over time

Graph starts empty, edges are added one by one

Incremental MSF problem

add\_edge(u, v, w): add edge with cost w between vertices u and
 get\_anf(): return a list with the edges of an MSF of G

- 1. So, this brings us to the Incremental MSF problem. The goal is to maintain a Minimum Spanning Forest in a graph that grows over time.
- 2. Crucially, the graph starts empty, and edges are only added one by one.
- 3. ——- SKIP SLIDE ——-

• **Key insight:** Use link-cut trees to maintain MSF dynamically

2025-

Partial to full retroactivity

Frederickson's link-cut tree solution

rederickenn's link-out tree solution

- 1. So, what was Frederickson's solution? He showed that link-cut trees can efficiently maintain this incrementing forest. ———- SKIP SLIDE
- 2. Link-cut trees provide all the operations we need, all in  $O(\log n)$ amortized time: find\_max to find the most expensive edge on a path, link to add a weighted edge, cut to remove one, and is onnected to check if u and v are in the same component
- 3. ———- SKIP SLIDE ———-
- 4. With this, we can construct a straightforward algorithm that supports adding a new edge (u, v, w):
- 5. First, we check if u and v are already connected. If they're not, the new edge can't create a cycle, so we just add it to the forest using link.
- 6. If they \*are\* connected, adding this new edge creates a cycle. We find the most expensive edge on the path in that cycle using find\_max.
- 7. If our new edge's cost w is cheaper than that maximum cost, we swap them: we cut the old, expensive edge and link our new, cheaper edge .
- 8. ——- SKIP SLIDE ——-
- 9. With these steps using LCT operations, the time per edge addition is  $O(\log n)$  amortized.

• **Key insight:** Use link-cut trees to maintain MSF dynamically

#### • Link-cut tree operations:

- ▶ find\_max(u, v):  $O(\log n)$  amortized
- ▶ link(u, v, w):  $\mathcal{O}(\log n)$  amortized
- $ightharpoonup \operatorname{cut}(u,v)$ :  $\mathcal{O}(\log n)$  amortized
- ▶ is\_connected(u, v):  $\mathcal{O}(\log n)$  amortized

# Incremental MSF example - Step 1

• add\_edge(g, h, 4): Add edge (g, h) with cost 4

G C

• MSF: {g-h}

Partial to full retroactivity

2025-10-30

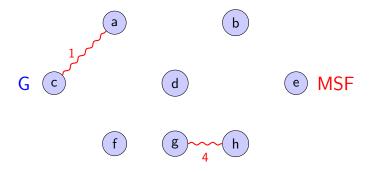

☐Incremental MSF example - Step 1

- 1. Let's walk through a quick example. We start with an empty graph.
- 2. First, we add edge (g, h) with cost 4.
- 3. Are 'g' and 'h' connected? No. So, by step 2 of the algorithm, we simply add the edge to our MSF.
- 4. The MSF is now just {g-h}.

## Incremental MSF example - Step 2

• add\_edge(c, a, 1): Add edge with cost 1

• MSF: {g-h, c-a}

Partial to full retroactivity

2025-10-30

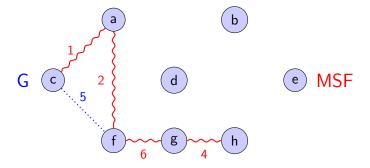

└─Incremental MSF example - Step 2

- 1. Next, we add (c, a) with cost 1.
- 2. Again, are 'c' and 'a' connected? No. They are in a different component from 'g' and 'h'.
- 3. So, we add it directly. The MSF now has two components:  $\{g-h\}$  and  $\{c-a\}$ .

# Incremental MSF example - Step 3 (Cycle Check)

• add\_edge(c, f, 5): Add edge with cost 5

• **MSF:** {g-h, c-a, f-g, a-f}

Partial to full retroactivity

└─Incı

2025-1

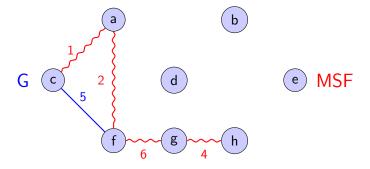

Incremental MSF example - Step 3 (Cycle Check)

- 1. After fast-forwarding through a few steps (adding f-g and a-f), our forest is more connected.
- 2. Now, we add (c, f) with cost 5. This is our first interesting case.
- 3. Are 'c' and 'f' connected? Yes, they are. Adding this edge will create a cycle: c-a-f-c.
- 4. So, we go to step 3. We find the max-cost edge on the path c-a-f. The edges are (c,a) with cost 1 and (a,f) with cost 2. The max cost is 2.

## Incremental MSF example - Step 3 (Result)

• add\_edge(c, f, 5): Edge is ¿ max cost (2), not added

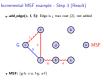

• MSF: {g-h, c-a, f-g, a-f}

Partial to full retroactivity

2025-10-30

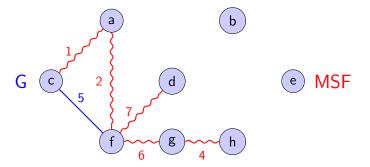

└─Incremental MSF example - Step 3 (Result)

- 1. Our new edge costs 5. Since 5 is \*not\* less than the max cost of 2, we \*do not\* add this edge. It's discarded.
- 2. The MSF remains unchanged.

## Incremental MSF example - Step 4

• add\_edge(f, d, 7): Add edge with cost 7

• MSF: {g-h, c-a, f-g, a-f, f-d}

Partial to full retroactivity

2025-10-30

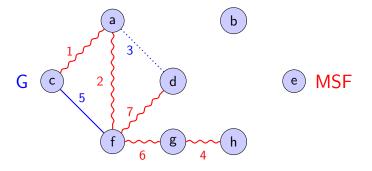

└─Incremental MSF example - Step 4

- 1. Next, add (f, d) with cost 7.
- 2. Are 'f' and 'd' connected? No. 'f' is in the main tree, but 'd' is a new, isolated vertex.
- 3. Therefore, we simply add the edge. The MSF is updated.

# Incremental MSF example - Step 5 (Cycle Check)

• add\_edge(a, d, 3): Add edge with cost 3

• MSF: {g-h, c-a, f-g, a-f, f-d}

Partial to full retroactivity

2025-10-30

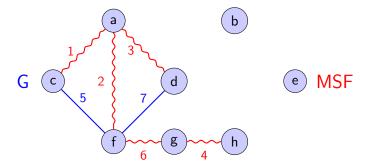

☐ Incremental MSF example - Step 5 (Cycle Check)

- 1. Now, add (a, d) with cost 3.
- 2. Are 'a' and 'd' connected? Yes. This creates the cycle a-f-d-a.
- 3. We find the max-cost edge on the path a-f-d. The edges are (a,f) with cost 2 and (f,d) with cost 7. The max cost is 7.

# Incremental MSF example - Step 5 (Result)

• add\_edge(a, d, 3): Cost 3 i max cost 7, swap edges

• MSF: {g-h, c-a, f-g, a-f, a-d}

Partial to full retroactivity

2025-10-30

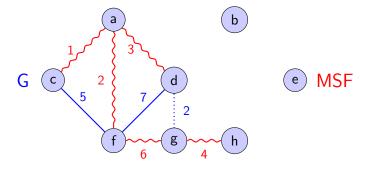

└─Incremental MSF example - Step 5 (Result)

- 1. Our new edge costs 3. Since 3 \*is\* less than 7, we swap them.
- 2. We 'cut' the expensive edge (f,d) and 'link' our new, cheaper edge (a,d).
- 3. The MSF is now  $\{g-h, c-a, f-g, a-f, a-d\}$  and its total cost has improved.

# Incremental MSF example - Step 6 (Cycle Check)

• add\_edge(d, g, 2): Add edge with cost 2

• MSF: {g-h, c-a, f-g, a-f, a-d}

Partial to full retroactivity

2025-10-30

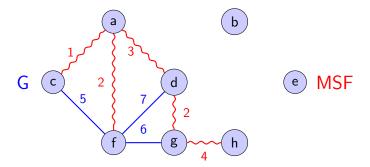

Incremental MSF example - Step 6 (Cycle Check)

- 1. Finally, let's add (d, g) with cost 2.
- 2. Are 'd' and 'g' connected? Yes. This creates the cycle d-a-f-g-d.
- 3. We find the max-cost edge on the path d-a-f-g. The edges are (d,a) cost 3, (a,f) cost 2, and (f,g) cost 6. The max cost is 6, from edge (f,g).

# Incremental MSF example - Step 6 (Result)

• add\_edge(d, g, 2): Cost 2 i max cost 6, swap edges

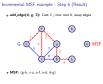

• MSF: {g-h, c-a, a-f, a-d, d-g}

Partial to full retroactivity

2025-10-30

☐ Incremental MSF example - Step 6 (Result)

- 1. Our new edge costs 2. Since 2 \*is\* less than 6, we swap them.
- 2. We 'cut' edge (f,g) and 'link' our new edge (d,g).
- 3. The MSF is updated again, and the total cost is now 12.

# Incremental MSF example - Step 7 (Final Result)

• Continue adding edges...

Partial to full retroactivity

o Continue adding edges...

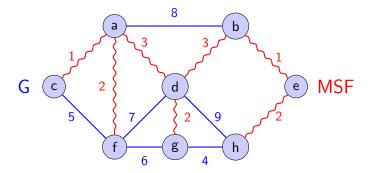

2025-10-30

Incremental MSF example - Step 7 (Final Result)

- 1. If we continue this process, adding all the remaining edges from our original graph...
- 2. ——- SKIP SLIDE ——-
- 3. ...we would eventually arrive at the final, optimal Minimum Spanning Tree. The one shown here, for example, has a total cost of 12.
- 4. But this only answers queries about the \*present\*. What if we want to ask: "What did the MSF look like 10 updates ago?"
- 5. This is the core question of retroactivity. How do we efficiently query the past?

# Incremental MSF example - Step 7 (Final Result)

- Continue adding edges...
- Final MSF: Minimum spanning forest with optimal cost

• Solution: Frederickson (1983) using link-cut trees

- 5. This is the core question of retroactivity. How do we efficiently query the past?

## What is retroactivity?

• Problem: Data structures usually support updates and queries

• The order of updates affects the state of the data structure

Partial to full retroactivity

└─What is retroactivity?

2025-

Problem: Data structures usually support updates and queries
 The order of updates affects the state of the data structure

What is retroactivity?

- 1. In a normal data structure, the order of updates is important. Most of the time, the state of the structure, and thus the answers to queries, depends on this sequence.
- 2. This means we usually don't have a good way to go back and correct mistakes or insert operations we forgot.
- 3. ———- SKIP SLIDE ———-
- 4. That's where retroactivity comes in. A retroactive data structure allows us to manipulate this sequence of updates.
- 5. ——- SKIP SLIDE ——-
- 6. Specifically, it adds operations to: Insert a new update at some time t \*in the past\*...
- 7. ...Remove an update that \*already happened\* at time t....
- 8. ...and, most importantly, Query the state of the structure at \*any\* time t, not just the present.
- 9. The key challenge is how to do this efficiently, maintaining the state for every possible time.

#### What is retroactivity?

• Problem: Data structures usually support updates and queries

• The order of updates affects the state of the data structure

• Retroactivity: Manipulate the sequence of updates

What is retroactivity?

What is retroactivity?

Problem: Data structures usually support updates and queries

The order of updates affects the state of the data structu

Retroactivity: Manipulate the sequence of updater

Operations:

- Insert update at time t (possibly in the past)
   Remove update at time t
   Query at time t (not just present)
- 1. In a normal data structure, the order of updates is important. Most of the time, the state of the structure, and thus the answers to queries, depends on this sequence.
- 2. This means we usually don't have a good way to go back and correct mistakes or insert operations we forgot.
- 3. ———- SKIP SLIDE ———-
- 4. That's where retroactivity comes in. A retroactive data structure allows us to manipulate this sequence of updates.
- 5. ——- SKIP SLIDE ——-
- 6. Specifically, it adds operations to: Insert a new update at some time t \*in the past\*...
- 7. ...Remove an update that \*already happened\* at time t....

# Demaine, Iacono & Langerman's solution

#### Theorem (Theorem 05)

Any partially retroactive data structure can be transformed into a fully retroactive one with:

- $\mathcal{O}(\sqrt{m})$  slowdown per operation
- $\mathcal{O}(m)$  space usage
- **Requirement:** *Need persistent version of the data structure*

Where m is the number of updates.

LAGOS 25 - November 10-14, 2025

Partial to full retroactivity

Any partially retroactive data structure can be transformed into a full-Requirement: Need persistent version of the data structure

Demaine, Iacono & Langerman's solution

2025-

Demaine, Iacono & Langerman's solution

- 1. Their paper presented this theorem: any partially retroactive data structure can be made fully retroactive.
- 2. The cost is an  $O(\sqrt{m})$  slowdown per operation and O(m) space, where *m* is the number of updates.
- 3. But there's a catch: this transformation \*requires\* a persistent version of the data structure.
- 4. ——- SKIP SLIDE ——-
- 5. So, how does it work? The idea is to break the m updates into  $\sqrt{m}$ blocks, each of size  $\sqrt{m}$ .
- 6. At the beginning of each block, we store a "checkpoint" of the data structure's state.
- 7. ——- SKIP SLIDE ——-
- 8. Now, to query at some time *t*:
- 9. First, we find the closest checkpoint \*before\* t. We load this saved state.
- 10. Then, we "roll forward" by applying all the updates between that checkpoint and time t. There are at most  $\sqrt{m}$  of them.
- 11. We answer the query, and then we "roll back" the changes to restore the checkpoint, which is where persistence comes in handy.

Limitations → Key Insight

Our dynamic goal and solution

Goal: Remove the Fixed m dependency while preserving time comple

• Key Insight: Introduce a \*\*dynamic rebuilding process\*\* to har

arbitrary growth. • Challenge: Rebuilding  $\sqrt{m}$  checkpoints must be fast, avoiding

complex persistent data structures.

• Solution: \*\*Reuse\*\* the existing data structures to efficient!

econstruct new checkpoints

- 1. The existing approach is based on a static constraint: we must assume a fixed *m*.
- 2. This means you have to know the total number of operations in advance.
- 3. Crucially, they lack a mechanism for \*\*rebuilding\*\*, making them unable to handle a growing or unknown number of operations.
- 4. Our goal is simple: remove the dependence on a fixed *m* while keeping the time efficiency.
- 5. Our key insight is to introduce a \*\*dynamic rebuilding process\*\* to handle growth.
- 6. The challenge is doing this efficiently. Rebuilding  $\sqrt{m}$  checkpoints non-persistently usually takes too long.
- 7. Our solution is a clever trick: we \*\*reuse\*\* the data structures already present in our system to reconstruct new checkpoints quickly.

- Key idea: Reuse existing data structures during rebuilding
- **Rebuilding moments:** When  $m = k^2$  (perfect square)

Our solution - Rebuilding strategy

Our solution - Rebuilding strategy

c Reuse existing data structures during rebuild ag moments: When  $m = k^2$  (perfect square)

- 1. Here's our strategy. The key idea is to reuse the existing structures.
- 2. We trigger a rebuild whenever the total number of operations, m, becomes a perfect square, say  $k^2$ .
- 4. When we rebuild, we're going from k checkpoints to k+1 new ones. Our strategy is:
- 5. 1. We create two new, \*empty\* structures,  $D'_0$  and  $D'_1$ .
- 6. 2. Then, we \*reuse\* our old structures: the old  $D_0$  becomes the new  $D_2'$ , the old  $D_1$  becomes the new  $D_3'$ , and so on. We shift them over by two spots.
- 7. 3. Finally, we just apply the "missing" updates to each of these reused structures to get them up to date for their new checkpoint times.
- 8. ——- SKIP SLIDE ——-
- 9. The reason this is efficient is based on a key lemma we prove: The updates needed for the new  $D'_{i+2}$  are just a continuation of the updates from the old  $D_i$ . We don't have to restart from scratch.
- 10. ——- SKIP SLIDE ——-
- 11. This rebuilding process takes  $O(m \log n)$  time in total.

- **Key idea:** Reuse existing data structures during rebuilding
- Rebuilding moments: When  $m = k^2$  (perfect square)
- Strategy:
  - Create new empty structures  $D_0', D_1'$
  - 2 Reuse  $D_i \rightarrow D'_{i+2}$  for  $i = 0, \dots, k-1$
  - 3 Apply missing updates to each  $D'_i$

- 7. 3. Finally, we just apply the "missing" updates to each of these reused structures to get them up to date for their new checkpoint times.
- 8. ——- SKIP SLIDE ——-
- 9. The reason this is efficient is based on a key lemma we prove: The updates needed for the new  $D'_{i+2}$  are just a continuation of the updates from the old  $D_i$ . We don't have to restart from scratch.
- 10. ———- SKIP SLIDE ———-
- 11. This rebuilding process takes  $O(m \log n)$  time in total.

- Key idea: Reuse existing data structures during rebuilding
- **Rebuilding moments:** When  $m = k^2$  (perfect square)
- Strategy:
  - Create new empty structures  $D'_0, D'_1$
  - 2 Reuse  $D_i \rightarrow D'_{i+2}$  for  $i = 0, \dots, k-1$
  - 3 Apply missing updates to each  $D'_i$

#### Key Lemma

Every update in  $D_i$  is within the first (i+2)(k+1) updates in the new sequence.

└Our solution - Rebuilding strategy

Our solution - Rebuilding strategy 

• Key Max. House switing data structures during shading 
• Balanding measures with  $m = k^2$  (parties square) 

• Strategy: 

• Game an - empty structure  $\Omega_{k}^{*}(L_{k}^{*})$  

• A structure of  $\Omega_{k}^{*}(L_{k}^{*})$  

• A result in the series of  $\Omega_{k}^{*}$  which the first (i+2)(k+1) updates in the new sequence.

- 1. Here's our strategy. The key idea is to reuse the existing structures.
- 2. We trigger a rebuild whenever the total number of operations, m, becomes a perfect square, say  $k^2$ .
- 3. ——- SKIP SLIDE ——-
- 4. When we rebuild, we're going from k checkpoints to k+1 new ones. Our strategy is:
- 5. 1. We create two new, \*empty\* structures,  $D'_0$  and  $D'_1$ .
- 6. 2. Then, we \*reuse\* our old structures: the old  $D_0$  becomes the new  $D_2'$ , the old  $D_1$  becomes the new  $D_3'$ , and so on. We shift them over by two spots.
- 7. 3. Finally, we just apply the "missing" updates to each of these reused structures to get them up to date for their new checkpoint times.
- 8. ——- SKIP SLIDE ——-
- 9. The reason this is efficient is based on a key lemma we prove: The updates needed for the new  $D'_{i+2}$  are just a continuation of the updates from the old  $D_i$ . We don't have to restart from scratch.

### Rebuilding algorithm

- $D_0' \leftarrow \text{NEWINCREMENTALMSF}()$
- $O_1' \leftarrow \text{NEWINCREMENTALMSF}()$
- **③** For i = 2 to k + 1:  $D'_i \leftarrow D_{i-2}$

- **4** For i = 1 to k + 1:
  - ▶  $p \leftarrow \text{KTH}(S, i(k+1))$   $\triangleright i(k+1)$ th item in the sequence of updates
  - ▶  $t_i' \leftarrow p$ .time
  - ▶ ADDEDGES( $S, t_{i-2}, t'_i, D'_i$ )
- **6** Return k + 1, D', t'

Partial to full retroactivity

Rebuilding algorithm

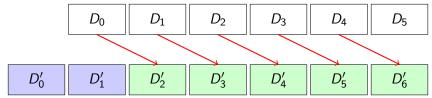

- 1. This slide shows the algorithm in more detail.
- 2. Lines 1 and 2 create the two new empty structures,  $D'_0$  and  $D'_1$ .
- 3. Line 3 is the reuse: we loop from i = 2 up to k + 1, and simply assign the old  $D_{i-2}$  to be the new  $D'_i$ . This is just a pointer swap; it's instant.
- 4. Line 4 is where the work happens. We loop through our new structures and apply the missing updates to each one, from its old checkpoint time  $t_{i-2}$  to its new checkpoint time  $t'_i$ .
- 5. ——- SKIP SLIDE ——-
- 6. The diagram at the bottom visualizes this reuse. The new  $D'_0$  and  $D'_1$  are built from scratch, but all the others,  $D'_2$  through  $D'_{k+1}$ , are just the old  $D_0$  through  $D_{k-1}$ , shifted over and updated.
- 7. Again, this gives us the  $O(\sqrt{m} \log n)$  amortized time...
- 8. ...but it requires  $\Theta(m\sqrt{m})$  space, because we are storing these  $\sqrt{m}$  independent copies.

### Results

#### Our contribution

- ullet General transformation: Partial o Full retroactivity
- No persistent data structures needed
- Same time complexity:  $\mathcal{O}(\sqrt{m})$  per operation
- Space trade-off:  $\Theta(m\sqrt{m})$  vs  $\mathcal{O}(m)$

Partial to full retroactivity

L

r contribution

• General transformation: Partial → Full retroactivity

• No persistent data structures needed

• Same time complexity:  $O(\sqrt{m})$  per operation

• Soace trade-off:  $\Theta(m/m)$  vs O(m)

Results

- 1. So, to summarize our contributions:
- 2. We've developed a general transformation to take a partially retroactive data structure and make it fully retroactive.
- 3. Crucially, our method \*does not require persistent data structures\*.
- 4. We match the  $O(\sqrt{m})$  slowdown per operation from the Demaine et al. paper...
- 5. ...at the cost of  $\Theta(m\sqrt{m})$  space, which we argue is a very practical trade-off for simplicity.
- 6. ——- SKIP SLIDE ——-
- 7. Applying this to our test case, we get a semi-retroactive MSF implementation.
- 8. It supports adding edges and querying the MSF at any time t in  $O(\sqrt{m}\log n)$  amortized time.
- 9. And, we have successfully removed the limitations from the previous work: our structure works \*without\* a fixed *m* or a fixed time range.

### Results

#### Our contribution

- **General transformation:** Partial → Full retroactivity
- No persistent data structures needed
- Same time complexity:  $\mathcal{O}(\sqrt{m})$  per operation
- Space trade-off:  $\Theta(m\sqrt{m})$  vs  $\mathcal{O}(m)$

#### Semi-retroactive MSF implementation

- Operations:  $add\_edge(u, v, w, t)$ ,  $get\_msf(t)$
- Time:  $\mathcal{O}(\sqrt{m}\log n)$  per operation
- Space:  $\Theta(m\sqrt{m})$
- No fixed m or time range restrictions

Partial to full retroactivity

└─Results

Thank you!

Questions?

- 1. Invite questions from the audience
- 2. Be prepared to answer questions about:
- 3. \* The rebuilding algorithm details
- 4. \* Space vs time trade-offs
- 5. \* Implementation challenges
- 6. \* Comparison with persistent data structures
- 7. \* Applications beyond MSF
- 8. Key points to emphasize if asked:
- 9. \* Our approach is simpler to implement
- 10. \* Same time complexity as Demaine et al.
- 11. \* No persistent data structure requirement
- 12. \* General applicability to any partially retroactive structure
- 13. Thank the audience for their attention
